

# Shapeless 101

Shapeless is an advanced functional programming library for the scala language.

# Disclaimer

This talk is adressed to complete beginners in Shapeless.

# Libraries that use shapeless

- **Specs2** : software specifications - testing
- **Spray Routing** : RESTful web services on top of Akka
- **Breeze** : numerical processing
- **Ammonite** : scala scripting

# Libraries that use shapeless

- **Circe** : JSON library that provides generic codec derivation using Shapeless.
- **Ficus** : wrapper companion for Typesafe config
- **ReactiveMongo** : non-blocking and asynchronous mongo driver
- **Finch** : purely functional basic blocks atop of Finagle

# Libraries that use shapeless

- **Refined** : refinement types with type-level predicates
- **Parboiled** : parsing library for arbitrary input text based on Parsing expression grammars
- **Monocle** : Optics library
- **Phantom** : driver for Cassandra

# Libraries that use shapeless

- **Scalacheck** : automated property-based testing
- **Quasar** : NoSQL analytics engine
- **Enum** : enumeration toolbox for Scala
- **Ensieme** : IDE-like features to a text editor

# Libraries that use shapeless

- **Scodec** : combinator library for working with binary data
- **Anorm** : data access layer
- **Doobie** : principled database access
- **Scala Exercises** : learning tool

- example: how to convert the parameters of a case class to a map using shapeless.

# Type-level scala programming

just a hint

```
def bla(v:String):String = ???  
// v is value parameter
```

```
def bla2[A](v:A):A = ???  
// v is value parameter and A is type parameter
```

# Type-level scala programming

*more at*

[Type-Level Programming in Scala](#)

# Heterogenous Lists

A List containing elements of different types and retains the type of each element in its own type

```
sealed trait HList
case object HNil extends HList
case class ::[H, T <: HList](head: H, tail: T)
      extends HList
```

# Heterogenous Lists

How to use it ?

```
import shapeless._  
val hlist = 26 :: "Harry" :: HNil
```

# Heterogenous Lists

## HList methods

- `map`
- `flatMap`
- `foldLeft` (and other fold operations)
- `zipper`
- `unify`
- `toList`

# Heterogenous Lists

*more at*

[Shapeless features overview : Heterogenous lists](#)

# The `Generic[T]` object

A `Generic[T]` object implements the methods

- `to(t:T):HList`
- `from(hl:HList):T`

for a given product type (usually, a case class or a tuple).

# The Generic[T] object

## case class

```
import shapeless._

case class Person(name:String, age:Int)
val gp = Generic[Person]
val harry = Person("Harry", 39)
val hl: String :: Int :: HNil = gp.to(harry)
val p: Person = gp.from(hl)
assert( harry == p )
```

# The Generic[T] object

## tuple

```
import shapeless._

val gp = Generic[Tuple2[String,Int]]
val harryTuple = ("Harry", 39)
val hl: String :: Int :: HNil = gp.to(harryTuple)
val tp: Tuple2[String,Int] = gp.from(hl)
assert(harryTuple == tp)
```

# Higher Kinds and Type Constructors

List

is a **type constructor**, it takes one type parameter

*notation:* `* -> *`

--

List[String]

is a **type**, produced by a type constructor `List` using type parameter `String`

*notation:* `*`

# Higher Kinds and Type Constructors

## Type Constructors

Option, Future, F[\_]

## Types

Option[Int], Future[String], F[A]

# Natural Transformations

```
trait NatT[F[_], G[_]] { def apply[T](f : F[T]) : G[T] }
```

or

```
F ~> G
```

This is very similar to Function1 but for type constructors.

# Natural Transformations

## Function1

```
val f : A => B = ???
```

## Natural Transformation

```
val nat : F ~> G
```

or

```
val nat : F[A] => G[A]
```

# Polymorphic functions

a simple case of natural transformation

```
import poly._  
  
object choose extends (Set ~> Option) {  
  def apply[T](s : Set[T]) = s.headOption  
}
```

```
scala> choose(Set(1, 2, 3))  
res0: Option[Int] = Some(1)  
  
scala> choose(Set('a', 'b', 'c'))  
res1: Option[Char] = Some('a')
```

# Polymorphic functions

via type classes

```
// size is a function from Ints or Strings or pairs to a  
// by type specific cases
```

```
object size extends Poly1 {  
  implicit def caseInt = at[Int](x => 1)  
  implicit def caseString = at[String](_.length)  
  implicit def caseTuple[T, U]  
    (implicit st : Case.Aux[T, Int],  
     su : Case.Aux[U, Int]) =  
    at[(T, U)](t => size(t._1)+size(t._2))  
}
```

# Polymorphic functions

```
scala> size(23)  
res4: Int = 1
```

```
scala> size("foo")  
res5: Int = 3
```

```
scala> size((23, "foo"))  
res6: Int = 4
```

```
scala> size(((23, "foo"), 13))  
res7: Int = 5
```

# Polymorphic functions

```
//Polymorphic addition with type specific cases  
object plus extends Poly2 {  
  implicit val caseInt = at[Int,Int](_+_)  
  implicit val caseDouble = at[Double,Double](_+_)  
  implicit val caseString = at[String,String](_+_)  
  implicit def caseList[T] = at[List[T],List[T]](_:::_)  
}
```

```
scala> plus(1,1)  
res1: plus.caseInt.Result = 2
```

```
scala> val p = plus ("foo", "bar")  
p: plus.caseString.Result = foobar
```

```
scala> val p1 :String = plus ("foo", "bar")  
p1: String = foobar
```

```
scala> p1==p  
res6: Boolean = true
```

# Product and Coproduct

# Product

From Wikipedia: In category theory, the product of two (or more) objects in a category is a notion designed to capture the essence behind constructions in other areas of mathematics such as the cartesian product of sets, the direct product of groups, the direct product of rings and the product of topological spaces.

$$\begin{array}{ccccc} & & Y & & \\ & \swarrow f_1 & | f & \searrow f_2 & \\ X_1 & \xleftarrow{\pi_1} & X_1 \times X_2 & \xrightarrow{\pi_2} & X_2 \end{array}$$

# Coproduct

From Wikipedia: In category theory, the coproduct, or categorical sum, is a category-theoretic construction which includes as examples the disjoint union of sets and of topological spaces, the free product of groups, and the direct sum of modules and vector spaces.

$$\begin{array}{ccccc} & & Y & & \\ & \nearrow f_1 & \uparrow f & \nwarrow f_2 & \\ X_1 & \xrightarrow{i_1} & X_1 \amalg X_2 & \xleftarrow{i_2} & X_2 \end{array}$$

# Product and Coproduct

What ????

## Product

Think of **AND**

example: A tuple is a product

```
val product : (String,Int) = ???
```

## Coproduct

Think of OR

example : sealed traits

```
sealed trait Animal
case class Dog(name:String) extends Animal
case class Cat(name:String) extends Animal
```

# Product and Coproduct

Learn the **different names** of the Product and Coproduct . For example when you need to import `Keys` typeclass for a case class and the ide suggests **`shapeless.ops.record._`** and **`shapeless.ops.union._`** in order to choose you need to know

# Product and Coproduct

<b>Product</b>	<b>Coproduct</b>
record	sum (type)
tuple	(tagged / disjoint) union

# Product and Coproduct

**more resources**

[Alissa Pajer - Products, limits and more!](#)

[Category Theory for the Working Hacker](#)

# The Aux Pattern

A simple type with one type parameter

```
trait Foo[A] {  
  type B  
  def value : B  
}
```

# The Aux Pattern

So let's define some instances:

```
implicit def fi = new Foo[Int] {  
  type B = String  
  val value = "Foo"  
}  
  
implicit def fs = new Foo[String] {  
  type B = Boolean  
  val value = false  
}
```

# The Aux Pattern

```
def foo[T](t: T)(implicit f: Foo[T]): f.B = f.value  
  
val res1: String = foo(2)  
val res2: Boolean = foo(" ")
```

So far, so good

# The Aux Pattern

But what happens if we want to use the **return type** as a **type parameter** in a type constructor ???

```
import scalaz._, Scalaz._

def foo[T](t: T)
  (implicit f: Foo[T],
   m: Monoid[f.B]): f.B = m.zero
```

gives compiler error

```
illegal dependent method type: parameter appears in the
type of another parameter in the same section
or an earlier one
```

# The Aux Pattern

Aux is just a way to extract the result of a type level computation.

```
type Aux[A0, B0] = Foo[A0] { type B = B0 }
```

and it works now:

```
def foo[T, R](t: T)(implicit f: Foo.Aux[T, R],  
                      m: Monoid[R]): R = m.zero  
val res1: String = foo(2)  
val res2: Boolean = foo('')
```

# The Aux Pattern

## **more resources**

[The Aux Pattern \(A short introduction to the Aux pattern \)](#)

[Aux Pattern Evolution](#)

# Singleton type

```
val a: Int = 26
```

This is an `Int` . Right ?

Internally in scalac represented as `Int(26)`

But only internally, we cannot access this type.

# Singleton type

But we can use shapeless Singleton type

```
import shapeless._, syntax.singleton._  
  
val b = 26.narrow
```

```
b: Int(26) = 26
```

b is of type `Int(26)`

which is a subclass of Int `Int(26) <: Int`

# Singleton type

- A singleton type is a type for which there exists exactly one value. ex: `Int(26)`
- we can now lift values into the type system.

# Witness

We can go also the other way.

To get a value from a singleton type.

With `witness` .

# Witness

If we have a witness for a singleton type in scope  
It will produce the value corresponding to a singleton type.

```
scala> val c = Witness(26)
c: shapeless.Witness.Aux[Int(26)] = shapeless.Witness$$anon$1

scala> c.value
res3: c.T = 26
```

# LabelledGeneric

Do you remember `Generic` ?

Labellegeneric is similar but with "labels". :)

So it also implements the methods

- `to(t:T):HList`
- `from(hl:HList):T`

# LabelledGeneric

```
case class Rectangle(width: Int, height: Int)
val genRectangle = LabelledGeneric[Rectangle]
val hlist = genRectangle.to(Rectangle(1,3))
//nothing changed until here
hlist.get('width)
```

```
res1: Int = 1
```

# LabelledGeneric

```
val modified = repr.updated('height', 42)  
genRectangle.from(modified)
```

```
res4: Rectangle = Rectangle(1,42)
```

# LabelledGeneric

another example

```
import shapeless._
import shapeless.ops.record._

case class Foo(bar: String, baz: Boolean)

val lbl = LabelledGeneric[Foo]
val keys = Keys[lbl.Repr].apply
```

```
scala> println(keys)
'bar :: 'baz :: HNil
```

```
scala> println(keys.toList.map(_.name))
List(bar, baz)
```

# LabelledGeneric

more for LabelledGeneric - Singleton Type - Witness Type

[labelled generic example in github shapeless](#)

[Shapeless : not a tutorial - part 2](#)

[Shapeless for Mortals](#)

# example

How to convert the parameters of a case class to a map using shapeless.

You could use shapeless.

# example

Let

```
case class X(a: Boolean, b: String, c: Int)
case class Y(a: String, b: String)
```

# example

Define a LabelledGeneric representation

```
import shapeless._
import shapeless.ops.product._
import shapeless.syntax.std.product._

object X {
  implicit val lgenX = LabelledGeneric[X]
}

object Y {
  implicit val lgenY = LabelledGeneric[Y]
}
```

# example

Define a typeclass to provide the toMap methods

```
object ToMapImplicits {  
  implicit class ToMapOps2[A <: Product](val a: A)  
  extends AnyVal {  
    def mkMap(implicit toMap: ToMap.Aux[A, Symbol, Any])  
      a.toMap[Symbol, Any]  
      .map { case (k: Symbol, v) =>  
        k.name -> v.toString }  
  }  
}
```

# example

Then you can use it like this.

```
object Run extends App {  
  import ToMapImplicits._  
  val x: X = X(true, "bike", 26)  
  val y: Y = Y("first", "second")  
  
  val mapX: Map[String, String] = x.mkMap  
  val mapY: Map[String, String] = y.mkMap  
  println("mapX = " + mapX)  
  println("mapY = " + mapY)  
}
```

which prints

```
mapX = Map(c -> 26, b -> bike, a -> true)  
mapY = Map(b -> second, a -> first)
```

## example

This works for simple case classes.

For nested case classes, (thus nested maps) check [this answer in SO](#)

# Bonus : Scala as Prolog

From [A shapeless primer](#):

*how implicit variables, implicit functions, type parameters in functions and implicit parameter lists of functions can be "interpreted" in a rule-based context.*

<b>Scala</b>	<b>Prolog</b>
implicit vals	facts
implicit defs	rules
type parameters in def	variables in a rule
implicit parameter lists	bodies of a rule

# Shapeless 101 - Conclusions

- You don't know shapeless (yet)
- You should know the basics and should start making sense
- You can copy some code from Stackoverflow and understand some of it.
